

Flip-vs-faithful decision AUROC against passage length

959 CondaQA anchor pairs spliced into byte-identical real host passages; SPLICE arm, Wikipedia hosts, positions pooled.

-○- Dashed line, hollow marker: the passage exceeds the encoder's operative window, so the point re-scores one window-full of text and is not a measurement at the length its position names. Seven of ten truncate from 512 up, all-MiniLM-L6-v2 from 256, so inside the deployed-defaults band only the three nomic entries are still measuring length.

L*(AUROC=0.75) is left-censored at ≤64 for all ten configurations: none reaches usable discrimination at any length the grid can build.
